# Why another language?

<http://chapel.cray.com>

- High-level parallel programming language
  - ▶ “Python for parallel programming”
  - ▶ much easier to use and learn than MPI; few lines of Chapel code typically replace tens of lines of MPI code
  - ▶ abstractions for data distribution/parallelism, task parallelism
  - ▶ optimization for data-driven placement of subcomputations
  - ▶ granular (“multi-resolution”) design: can bring closer to machine level if needed
  - ▶ everything you can do in MPI (and OpenMP!), you should be able to do in Chapel
- Focus on performance
  - ▶ compiled language; simple Chapel codes perform as well as optimized C/C++/Fortran code
  - ▶ reportedly, very complex Chapel codes run at  $\sim 70\%$  performance of a similar well-tuned MPI code (not bad, but room to improve)
- Perfect language for learning parallel programming for beginners
- Open-source: can compile on all Unix-like platforms, precompiled for MacOS (single-locale), Docker image (multi-locale)
- Fairly small community at the moment: too few people know/use Chapel  $\iff$  too few HPC centers install and promote it

# Our workshop

## PART 1: BASIC LANGUAGE FEATURES

- running single-locale Chapel codes on Cedar
  - ▶ interactive jobs vs. batch jobs
- quickly on running Chapel on your laptop
- problem description: heat transfer equation
- variables
- ranges and arrays
- conditionals
- `for` loops
- config variables
- timing code execution

collaborative notes  
<http://bit.ly/chapelone>

## PART 2: TASK PARALLELISM

- parallel concepts
  - ▶ concurrency vs. true parallelism
  - ▶ concurrency vs. locality
- fire-and-forget tasks
  - ▶ `begin` statement
  - ▶ `cobegin` statement
  - ▶ `coforall` loops
  - ▶ `forall` loops
- task synchronization
  - ▶ `sync` statement
  - ▶ sync variables
  - ▶ atomic variables
- parallelizing the heat transfer solver

## PART 3: DOMAIN PARALLELISM

- running multi-locale Chapel codes on Cedar
- simple multi-locale codes
- domains and single-locale data parallelism
- distributed domains
- heat transfer solver on distributed domains
- periodic boundary conditions
- writing to files

# Numerical problem: 2D heat transfer equation

- Imagine a metallic plate initially at 25 degrees
- Simple 2D heat (diffusion) equation

$$\frac{\partial T(x, y, t)}{\partial t} = \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2}$$

- Discretize the solution  $T(x, y, t) \approx T_{i,j}^{(n)}$  with  $i = 1, \dots, \text{rows}$  and  $j = 1, \dots, \text{cols}$ 
  - ▶ upper left corner is  $(1, 1)$ , lower right corner is  $(\text{rows}, \text{cols})$
- Initial condition:  $T_{i,j}^{(0)} = 25$
- Boundary condition: upper side  $T_{0,1..\text{cols}}^{(n)} \equiv 0$ , left side  $T_{1..\text{rows},0}^{(n)} \equiv 0$ ,  
bottom side  $T_{\text{rows}+1,1..\text{cols}}^{(n)} = 80 \cdot j/\text{cols}$ , right side  $T_{1..\text{rows},\text{cols}+1}^{(n)} = 80 \cdot i/\text{rows}$   
(linearly increasing from 0 to 80 degrees)
- Discretize the equation with forward Euler time stepping

$$\frac{T_{i,j}^{(n+1)} - T_{i,j}^{(n)}}{\Delta t} = \frac{T_{i+1,j}^{(n)} - 2T_{i,j}^{(n)} + T_{i-1,j}^{(n)}}{(\Delta x)^2} + \frac{T_{i,j+1}^{(n)} - 2T_{i,j}^{(n)} + T_{i,j-1}^{(n)}}{(\Delta y)^2}$$

# Numerical problem: 2D heat transfer equation (cont.)

- For simplicity assume  $\Delta x = \Delta y = 1$
- Use  $\Delta t = 1/4$
- The finite difference equation becomes

$$T_{i,j}^{(n+1)} = \frac{1}{4} \left[ T_{i+1,j}^{(n)} + T_{i-1,j}^{(n)} + T_{i,j+1}^{(n)} + T_{i,j-1}^{(n)} \right]$$

- The objective is to find  $T_{i,j}$  after a certain number of iterations, or when the system is in steady state
- Can increase the number of points in the grid to illustrate the advantage of parallelism

# Serial exercise: using *procedures* and control flow

Look up Chapel procedures

Write a Chapel code to find the root of the equation

$x^5 + 8x^3 - 2x^2 + 5x - 1.2 = 0$  using the bisection method in the interval  $[-1,1]$

- Calculate the function at the ends and the midpoint of the interval
- Depending on the signs of the three computed values, let the midpoint be either the new left or the new right end
- Repeat until your error is below  $\Delta x = 10^{-8}$

# Parallelism cheatsheet

- `for` is a serial loop; `a.. $\#n$`  means  $n$  iterations, `a.. $b$`  means  $b-a+1$  iterations
- `forall` loop is executed cooperatively by all local cores in parallel, or by remote locales that own the corresponding indices (subdividing their local iterations among their local cores); number of threads is equal to the number of available cores
- `coforall` loop creates a new task per each iteration (cycling through locales or tasks inside a locale)
- `begin { ... }` spins statements inside off into a new task
- `sync { ... }` pauses until the children have synced back up
- `cobegin { line1 line2 line3 }` runs each line in a new task; can be grouped with `{ }`
- Built-in variables and arrays
  - ▶ `numLocales` is the number of locales
  - ▶ `Locales` stores an array of compute nodes on which the program is executing
  - ▶ `locale.id` is the ID of the current locale
  - ▶ `locale.maxTaskPar` is the runtime maximum number of tasks on the current local
  - ▶ `locale.numCores` is the locale's number of compute cores
  - ▶ `locale.name` is a locale's name
  - ▶ `here` evaluates to the local on which the current task is running
- Distributions
  - ▶ `BlockDist` partitions indices into blocks according to a boundingBox domain and maps each block onto a separate locale
  - ▶ `CyclicDist` maps indices to locales in a round-robin pattern starting at a given index
  - ▶ `BlockCycDist`, `DimensionalDist2D`, `PrivateDist`, `ReplicatedDist`, `StencilDist`, `BlockCycDim`, `BlockDim`, `ReplicatedDim`

# Distributed domains
